Q: The bottom bounds of the two containers are equal. Why? I'm confused with the last example in this page. The bottom bounds of the two containers are equal. Why? A: The effect of changing the list example from A to B is that the top and the bottom of the frame are no longer equally spaced along the floor. This means that the boxes on top are no longer equally distant from the box on the bottom. To be precise, the top distance is the distance from the bottom of the box to the box on the bottom. The top distance is the same distance from the box on the bottom as it was before in example A. Whereas the bottom distance is the distance from the bottom of the box to the box on the bottom. The bottom distance has increased. If the two boxes were equally distant from the bottom, they'd have the same bottom distance. That's why the bottom distance has increased in B and the bottom bound has remained the same. Q: Error while calling inner join query I have the following query, which is used to get count of days between two dates. SELECT book.BookId, book.BookName, book.CreatedBy, date1.StartDay, date1.StartTime, date1.FinishDay, date1.FinishTime, date2.StartDay, date2.StartTime, date2.FinishDay, date2.FinishTime, date1.DayCount, date2.DayCount FROM book JOIN (SELECT TOP (1) daycount as
